

LESSON 4

DATA TYPES

Knowledge Has Organizing Power

Slides based on material from <https://javascript.info> licensed as [CC BY-NC-SA](#).
As per the CC BY-NC-SA licensing terms, these slides are under the same license.

Wholeness: All programs are organized in terms of data (information) and the operations that can be performed on it. *Science of Consciousness*: Programs are organized around different types of data and operations common to those types. Knowledge Has Organizing Power.

Main Points

1. Operations on primitive data types
 1. primitive wrappers
 2. numbers
 3. strings
2. Array operations
 1. Modify
 2. Search
 3. Transform

Main Point Preview:

Numbers, strings, and booleans each have special operations such as `parseInt`, `parseFloat`, `round`, `includes`, and `slice`.

7 basic data types in JavaScript

PRIMITIVES

1. **number** for numbers of any kind: integer or floating-point.
2. **string** for strings.
 1. A string may have one or more characters, there's no separate single-character type.
3. **boolean** for true/false.
4. **null** for unknown values – a standalone type that has a single value null.
5. **undefined** for unassigned values – a standalone type that has a single value undefined.
6. **symbol** for unique identifiers.

COMPLEX

1. **object** for more complex data structures.
 1. Arrays and functions are objects
- The typeof operator allows us to see which type is stored in a variable.
- Two forms: typeof x or typeof(x).
 - Returns a string with the name of the type, like "string".
 - For null returns "object" – this is an error in the language, it's not actually an object.

dynamic (loose) typing

- Dynamic typing
- JavaScript is a loosely typed or a dynamic language. Variables in JavaScript are not directly associated with any particular value type, and any variable can be assigned (and re-assigned) values of all types:

```
let foo = 42; // foo is now a number  
foo    = 'bar'; // foo is now a string  
foo    = true; // foo is now a boolean
```

A primitive as an object

- Here's the paradox faced by the creator of JavaScript:
 - There are many things one would want to do with a primitive like a string or a number. It would be great to access them as methods.
 - Primitives must be as fast and lightweight as possible.
- The solution looks a little bit awkward, but here it is:
 - Primitives are still primitive. A single value, as desired.
 - The language allows access to methods and properties of strings, numbers, booleans and symbols.
 - In order for that to work, a special “object wrapper” that provides the extra functionality is created, and then is destroyed.

```
let str = "Hello";  
alert( str.toUpperCase() ); // HELLO
```

A primitive as an object (2)

- what actually happens in `str.toUpperCase()`:
 - in the moment of accessing its property, a special object is created that knows the value of the string, and has useful methods, like `toUpperCase()`.
 - That method runs and returns a new string (shown by `alert()`).
 - The special object is destroyed, leaving the primitive `str` alone.
- So primitives can provide methods, but they still remain lightweight.let

```
let str = "Hello";  
alert( str.toUpperCase() ); // HELLO
```

- Exercise: **Can I add a string property?**

To write very big or very small numbers:

- Append "e" with the zeroes count to the number. Like: 123e6 is 123 with 6 zeroes.

```
let billion = 1e9; // 1 billion, literally: 1 and 9 zeroes  
alert( 7.3e9 ); // 7.3 billions (7,300,000,000)
```

```
1e3 = 1 * 1000  
1.23e6 = 1.23 * 1000000
```

- A negative number after "e" causes the number to be divided by 1 with given zeroes. That's for one-millionth or such.

```
let ms = 0.000001;  
let ms = 1e-6; // six zeroes to the left from 1
```

convert a string into an integer

- The `parseInt()` method converts a string into an integer (a whole number).
- It accepts two arguments. The first argument is the string to convert. The second argument is called the radix. This is the base number used in mathematical systems. For our use, it should always be 10.

```
let text = '42px';  
let integer = parseInt(text, 10);  
// returns 42
```

- If `parseInt` encounters a character that is not a numeral in the specified radix
 - ignores it and all succeeding characters
 - returns the integer value parsed up to that point. `parseInt`
 - truncates numbers to integer values

convert string argument to float

- `parseFloat()` method parses a string argument and returns a floating point

```
function circumference(r) {  
  if (isNaN(parseFloat(r))) {  
    return 0;  
  }  
  return parseFloat(r) * 2.0 * Math.PI;  
}
```

```
console.log(circumference('4.567abcdefgh'));  
// expected output: 28.695307297889173
```

```
console.log(circumference('abcdefgh'));  
// expected output: 0
```

convert number to string

```
const foo = 45;  
const bar = "" + foo;  
const bar2 = "" + 108;  
const bar3 = foo.toString();  
const bar4 = 108..toString(); //need both periods after number  
const bar5 = foo + "";  
console.log(typeof foo === "number"); //true  
console.log(typeof bar === "string"); //true  
console.log(typeof bar2 === "string"); //true  
console.log(typeof bar3 === "string"); //true  
console.log(typeof bar4 === "string"); //true  
console.log(typeof bar5 === "string"); //true
```

Rounding

- One of the most used operations when working with numbers is rounding.
 - several built-in functions for rounding:

	Math.floor	Math.ceil	Math.round	Math.trunc
3.1	3	4	3	3
3.6	3	4	4	3
-1.1	-2	-1	-1	-1
-1.6	-2	-1	-2	-1

exercises

- Sum numbers from the visitor
- Repeat until the input is a number
- An occasional infinite loop
- A random number from min to max
- A random integer from min to max

strings are contained in quotes

- Strings can be enclosed within either single quotes, double quotes or backticks:
 - `let single = 'single-quoted';`
 - `let double = "double-quoted";`
 - `let backticks = `backticks`;`

- Single and double quotes are essentially the same.

- Backticks allow us to embed any expression into the string, by wrapping it in `${...}`:

```
function sum(a, b) {  
  return a + b;  
}  
alert(`1 + 2 = ${sum(1, 2)}.`); // 1 + 2 = 3.
```

- Another advantage of using backticks is that they allow a string to span multiple lines:
- Our CS303 eslint convention is to require double quotes
 - Avoid's confusion with apostrophes
 - Compatible with JSON

Searching for a substring

- look for the substr in str,
 - starting from the given position pos,
 - returns the position where the match was found or -1 if nothing can be found.

```
let str = 'Widget with id';  
alert( str.indexOf('Widget') ); // 0, because 'Widget' is found at the beginning  
alert( str.indexOf('widget') ); // -1, not found, the search is case-sensitive  
alert( str.indexOf("id") ); // 1, "id" is found at the position 1 (..idget with id)
```

- **includes**, **startsWith**, **endsWith**
 - str.**includes**(substr, pos) returns true/false depending on whether str contains substr within.
 - right choice if we need to test for the match, but don't need its position:

```
alert( "Widget with id".includes("Widget") ); // true  
alert( "Hello".includes("Bye") ); // false
```

str.slice(start [, end])

- returns the part of the string from start to (but not including) end
- If there is no second argument, then slice goes till the end of the string

```
let str = "stringify";
```

```
alert( str.slice(0, 5) ); // 'strin', the substring from 0 to 5 (not including 5)
```

```
alert( str.slice(0, 1) ); // 's', from 0 to 1, but not including 1, so only character at 0
```

- other helpful methods in strings:
 - str.trim() – removes (“trims”) spaces from the beginning and end of the string.
 - str.repeat(n) – repeats the string n times.

exercises

- Uppercase the first character
- Check for spam
- Truncate the text
- Extract the money

Main Point:

Numbers, strings, and booleans each have special operations such as `parseInt`, `parseFloat`, `round`, `includes`, and `slice`.

Main Point Preview:

Arrays are used in almost every program. There are special methods for common operations on them including to modify, search, and transform arrays.

modify an array

- splice
- slice
- concat
- forEach

splice

- The `arr.splice(str)` method is a swiss army knife for arrays.
 - It can do everything: insert, remove and replace elements.
`arr.splice(index [, deleteCount, elem1, ..., elemN])`

- It starts from the position index:
 - removes `deleteCount` elements and then
 - inserts `elem1, ..., elemN` at their place.
 - Returns the array of removed elements.

deletion:

```
let arr = ["I", "study", "JavaScript"];  
arr.splice(1, 1); // from index 1 remove 1 element  
alert( arr ); // ["I", "JavaScript"]
```

MOTORCYCLE.COM

splice (2)

remove 3 elements and replace them with the other two:

```
let arr = ["I", "study", "JavaScript", "right", "now"];  
// remove 3 first elements and replace them with another  
arr.splice(0, 3, "Let's", "dance");  
alert( arr ) // now ["Let's", "dance", "right", "now"]
```

splice returns the array of removed elements:

```
let arr = ["I", "study", "JavaScript", "right", "now"];  
// remove 2 first elements  
let removed = arr.splice(0, 2);  
alert( removed ); // "I", "study" <-- array of removed elements
```

insert the elements without any removals.

```
let arr = ["I", "study", "JavaScript"];  
// from index 2  
// delete 0  
// then insert "complex" and "language"  
arr.splice(2, 0, "complex", "language");  
alert( arr ); // "I", "study", "complex", "language", "JavaScript"
```

slice

- returns a new array copying all items from index start to end
 - not including end

```
arr.slice(start, end)
```

```
let arr = ["t", "e", "s", "t"];  
console.log( arr.slice(1, 3) ); // ["e", "s"] (copy from 1 to 3)
```

concat

- returns new array that includes values from other arrays and additional items
 - accepts any number of arguments – either arrays or values.
 - result is a new array containing items from arr, then arg1, arg2 etc.
 - If an argument argN is an array, then all its elements are copied.
 - Otherwise, the argument itself is copied. `arr.concat(arg1, arg2...)`

```
let arr = [1, 2];
```

```
// create an array from: arr and [3,4]  
alert( arr.concat([3, 4])); // 1,2,3,4
```

```
// create an array from: arr and [3,4] and [5,6]  
alert( arr.concat([3, 4], [5, 6])); // 1,2,3,4,5,6
```

```
// create an array from: arr and [3,4], then add values 5 and 6  
alert( arr.concat([3, 4], 5, 6)); // 1,2,3,4,5,6
```

Iterate: forEach

- run a function for every element of the array.
 - result of the function (if it returns any) is thrown away and ignored
 - Intended for some side effect on each element of the array
 - print or alert or post to database

```
arr.forEach(function(item, index, array) {  
  // ... do something with item  
});
```

- shows each element of the array

```
// for each element call alert  
["Bilbo", "Gandalf", "Nazgul"].forEach(alert);
```

```
["Bilbo", "Gandalf", "Nazgul"].forEach((item, index, array) => {  
  alert(`${item} is at index ${index} in ${array}`);  
});
```

search an array

- indexOf/lastIndexOf and includes
- find and findIndex
- filter

indexOf/lastIndexOf and includes

- `arr.indexOf`, `arr.lastIndexOf` and `arr.includes` have same syntax and do essentially same as string counterparts
 - operate on items instead of characters:
 - `arr.indexOf(item, from)` – looks for item starting from index `from`, and returns the index where it was found, otherwise `-1`.
 - `arr.lastIndexOf(item, from)` – same, but looks for `from` right to left.
 - `arr.includes(item, from)` – looks for item starting from index `from`, returns `true` if found.

```
let arr = [1, 0, false];
```

```
alert( arr.indexOf(0) ); // 1
```

```
alert( arr.indexOf(false) ); // 2
```

```
alert( arr.indexOf(null) ); // -1
```

```
alert( arr.includes(1) ); // true
```

- use `===` comparison.
 - So, if we look for `false`, it finds exactly `false` and not the zero.
- If we want to check for inclusion, and don't want to know the exact index, then `arr.includes` is preferred.

filter

- Apply function to each item in array and return new array of all that pass the filter

```
let results = arr.filter(function(item, index, array) {  
  // if true item is pushed to results and the iteration continues  
  // returns empty array if nothing found  
});
```

```
let users = [  
  {id: 1, name: "John"},  
  {id: 2, name: "Pete"},  
  {id: 3, name: "Mary"}  
];  
// returns array of the first two users  
let someUsers = users.filter(item => item.id < 3);  
  
alert(someUsers.length); // 2
```

find and findIndex

- find an object that satisfies a specific condition

```
arr.find(function(item, index, array)
```

```
// if true is returned, item is returned and iteration is stopped
```

```
// for falsy scenario returns undefined
```

- The function is called for elements of the array, one after another:
 - item is the element.
 - index is its index.
 - array is the array itself.

```
//Let's find the one with id === 1:
```

```
let users = [
```

```
  {id: 1, name: "John"},
```

```
  {id: 2, name: "Pete"},
```

```
  {id: 3, name: "Mary"}]
```

```
];
```

```
let user = users.find(item => item.id === 1);
```

```
alert(user.name); // John
```

- arr.findIndex same but returns index where element found instead of element and -1 when nothing found.

transform an array

- map
- sort
- reverse
- reduce
- split / join

map

one of the most useful and often used.

It calls the function for each element of the array and returns the array of results.

```
let result = arr.map(function(item, index, array) {  
  // returns the new value instead of item  
});
```

```
let lengths = ["Bilbo", "Gandalf", "Nazgul"].map(item => item.length);  
alert(lengths); // 5,7,6  
//modify so that it alerts index: item.length instead of just item.length
```

sort(fn)

- sorts the array in place, changing its element order.
- returns sorted array, but the returned value is usually ignored, as arr itself is modified.
- Default sort converts all arguments to strings

```
let arr = [ 1, 2, 15 ];  
// the method reorders the content of arr  
arr.sort();  
alert( arr ); // 1, 15, 2
```

To use our own sorting order, we need to supply a function as the argument of arr.sort().

```
function compareNumeric(a, b) {  
  if (a > b) return 1;  
  if (a == b) return 0;  
  if (a < b) return -1;  
}  
let arr = [ 1, 2, 15 ];  
arr.sort(compareNumeric);  
alert(arr);
```

//EXERCISE: change comparator function to sort in descending order, then change it to sort in lexicographic descending order

sort(fn) [2]

- comparison function is only required to return
 - positive number to say “greater” and a
 - negative number to say “less”.
- That allows to write shorter functions:

```
let arr = [ 1, 2, 15 ];  
arr.sort(function(a, b) { return a - b; });  
alert(arr); // 1, 2, 15
```

Remember arrow functions? We can use them here for neater sorting:

```
arr.sort( (a, b) => a - b ); //same as above
```

reduce

calculate a single value based on the array.

```
let value = arr.reduce(function(previousValue, item, index, array) {  
  // ...  
}, [initial]);
```

The function is applied to all array elements one after another and “carries on” its result to the next call.

previousValue – is the result of the previous function call, equals initial the first time (if initial is provided).

item – is the current array item.

index – is its position.

array – is the array.

- first argument is the “accumulator” that stores the combined result of all previous execution.
 - at the end it becomes the result of reduce.
- CS303 convention: always include an initial value for clarity

reduce [2]

Here we get a sum of an array in one line:

```
let arr = [1, 2, 3, 4, 5];  
let result = arr.reduce(function (sum, current) { return sum + current; }, 0);  
let result2 = arr.reduce((sum, current) => sum + current, 0);  
console.log(result); // 15  
console.log(result2); // 15
```

- On the first run, sum is the initial value = 0, and current is first array element = 1
- On the second run, sum = 1, we add the second array element (2) to it and return.
- On the 3rd run, sum = 3 and we add one more element to it, and so on...

array methods

- To add/remove elements:
 - **push**(...items) – adds items to the end,
 - **pop**() – extracts an item from the end,
 - **shift**() – extracts an item from the beginning,
 - **unshift**(...items) – adds items to the beginning.
 - **splice**(pos, deleteCount, ...items) – at index pos delete deleteCount elements and insert items.
 - **slice**(start, end) – creates a new array, copies elements from position start till end (not inclusive) into it.
 - **concat**(...items) – returns a new array: copies all members of the current one and adds items to it. If any of items is an array, then its elements are taken.
- To search among elements:
 - **indexOf/lastIndexOf**(item, pos) – look for item starting from position pos, return the index or -1 if not found.
 - **includes**(value) – returns true if the array has value, otherwise false.
 - **find/filter**(func) – filter elements through the function, return first/all values that make it return true.
 - **findIndex** is like find, but returns the index instead of a value.
- To iterate over elements:
 - **forEach**(func) – calls func for every element, does not return anything.
- To transform the array:
 - **map**(func) – creates a new array from results of calling func for every element.
 - **sort**(func) – sorts the array in-place, then returns it.
 - **reverse**() – reverses the array in-place, then returns it.
 - **split/join** – convert a string to array and back.
 - **reduce**(func, initial) – calculate a single value over the array by calling func for each element and passing an intermediate result between the calls.

map/filter/find/reduce are “pure” functions

- Important principle of “functional” programming
- Pure functions have no side effects
 - Do not change state information
 - Do not modify the input arguments
- Take arguments and return a new value
- Valuable benefits for automated program verification, parallel programming, reuse, and readable code

'for in' over object literal/Arrays –ES6

```
//for in over Object  
//returns property keys (index) of object in  
  each iteration - arbitrary order
```

```
var things = {  
  'a': 97,  
  'b': 98,  
  'c': 99  
};  
  
for (const key in things) {  
  console.log(key + ', ' + things[key]);  
}
```

```
a, 97  
b, 98  
c, 99
```

'for of' vs 'for in' –ES6

- Both for..of and for..in statements iterate over arrays;
- for..in returns keys and works on objects as well as arrays
- for..of returns values of arrays but does not work with object properties

```
let letters = ['x', 'y', 'z'];
```

```
for (let i in letters) {  
  console.log(i); } // "0", "1", "2",
```

```
for (let i of letters) {  
  console.log(i); } // "x", "y", "z"
```

Summary 'for' loops

- 'for' is the basic for loop in JavaScript for looping
 - Almost exactly like Java for loop
 - Use this if you need the loop index
 - CS303 code convention: good to use meaningful loop index, but will allow i and j
- 'for in' is useful for iterating through the **properties of objects**
 - can also be used to go through the indices of an array (unusual use case)
- 'for of' is new convenience (ES6) method for 'iterable' collections
 - Array, Map, Set, String
 - Use this if usage involves a side effect and do not need loop index
- 'forEach' like for .. of but **executes a provided function** for each element.
 - forEach returns undefined rather than a new array
 - Intended use is **for side effects**, e.g., writing to output, etc.
- Best practice to use convenience methods when possible
 - Avoids bugs associated with indices at end points
 - **map, filter, find, reduce** best practice when appropriate

Main Point:

Arrays are used in almost every program. There are special methods for common operations on them including to modify, search, and transform arrays.

exercises

- Translate border-left-width to borderLeftWidth
- Filter range
- Filter range "in place"
- Sort in the reverse order
- Copy and sort array
- Create an extendable calculator
- Map to names
- Map to objects
- Sort users by age
- Shuffle an array
- Get average age
- Filter unique array members

CONNECTING THE PARTS OF KNOWLEDGE WITH THE WHOLENESS OF KNOWLEDGE

Knowledge Has Organizing Power

1. Numbers, strings, and arrays are important data types that have many common operations unique to their purpose and many methods in the language to support those operations.
 2. JavaScript arrays are highly flexible data structures with many built in methods.
-
3. **Transcendental consciousness.** Is the experience of total knowledge and perfect orderliness.
 4. **Impulses within the transcendental field:** Thoughts connected to the field of all the laws of nature will be supported by that level of total knowledge and coherence.
 5. **Wholeness moving within itself:** In unity consciousness one appreciates daily perceptions and experiences as being infused with order and purpose.
